
Python Basics

AI :- AI (artificial intelligence) is the ability of a digital computer or computer-controlled robot to perform tasks commonly associated with intelligent beings.

Arithmetic Operations :- Arithmetic operations are the basic calculations we make in everyday life like addition, subtraction, multiplication and division. It is also called as algebraic operations or mathematical operations.

Array of numbers :- Set of numbers or objects that follow a pattern presented as an arrangement of rows and columns to explain multiplication.

Assignment operator in Python :- Assignment operator is a type of Binary operator that helps in modifying the variable to its left with the use of its value to the right. The symbol used for assignment operator is "=".

Asterisk :- Symbol "*" used to perform various operations in Python.

Backslash :- A backslash is an escape character used in Python strings to indicate that the character immediately following it should be treated in a special way, such as being treated as escaped character or raw string.

Boolean :- Denoting a system of algebraic notation used to represent logical propositions by means of the binary digits 0 (false) and 1 (true).

Colon (:) :- A colon is used to represent an indented block. It is also used to fetch data and index ranges or arrays.

Data type :- Data type refers to the type of value a variable has and what type of mathematical, relational or logical operations can be applied without causing an error.

Double quote :- Symbol “ ” used to represent strings in Python.

Expression :- An expression is a combination of operators and operands that is interpreted to produce some other value.

Float :- Python float () function is used to return a floating-point number from a number or a string representation of a numeric value.

Forward slash :- Symbol “/” used to perform various operation in Python

Immutable :- Immutable Objects are of in-built datatypes like int, float, bool, string, Unicode, and tuple. In simple words, an immutable object can't be changed after it is created.

Integer :- An integer is the number zero (0), a positive natural number (1, 2, 3, and so on) or a negative integer with a minus sign (-1, -2, -3, and so on.)

Manipulate :- Is the process of modifying a string or creating a new string by making changes to existing strings.

Mathematical expressions :- Expressions in math are mathematical statements that have a minimum of two terms containing numbers or variables, or both, connected by an operator in between.

Negative indexing :- Allows you to access elements of a sequence (such as a list, a string, or a tuple) from the end, using negative numbers as indexes.

Operands :- The quantity on which an operation is to be done.

Operators in Python :- Operators are used to perform operations on variables and values.

Replicate :- To make an exact copy of.

Single quote :- Symbol ' ' used to represent strings in python.

Slicing in Python :- Slicing is used to return a portion from defined list.

Special characters :- A special character (@,\$,!,~,?,.....) is one that is not considered a number or letter. Symbols, accent marks, and punctuation marks are considered special characters.

Strings :- In Python, Strings are arrays of bytes representing Unicode characters.

Substring :- A substring is a sequence of characters that are part of an original string.

Type casting :- The process of converting one data type to another data type is called Typecasting or Type Coercion or Type Conversion.

Variables :- Variables are containers for storing data values.

Thank you
